I learned dynamic programming mainly from TopCoder (mostly by the tutorial). I find DP to be really helpful in solving a lot of problems and I have encountered some problems, which require some advanced techniques to be solved:

1) Reducing the inner cycle (or fully eliminating the inner cycle). As an example of such one is [this](#) [neal_wu](#)'s solution.

2) Using 'Convex hull' to speed up the transitions. An example of such a problem is 'acquire' from USACO Gold 2008 March.

I don't fully understand the first technique and I don't understand the second at all. I have looked over the solution to 'acquire', but I don't get it.

So here is my request:

Can someone put a link, or give a good description of these techniques (if there are others, mention them) and some problems to practice them on.

I am no expert in both techniques, but I just try to give few insight.

1) There has been a discussion in similar problems applying same technique in <http://forums.topcoder.com/?module=Thread&threadID=579321>. You can check that thread :)

2) Try to reduce the problems into: given set of points and gradients, find the minimum y-intercept for each gradient. Ignoring the sorting, this problem can be solved in $O(n)$. Another example problem is: <http://vn.spoj.pl/IOITRAIN/problems/NKLEAVES/en/> (thanks to [ktuan](#) who introduce me this problem :)

Another example problem is: <http://vn.spoj.pl/IOITRAIN/problems/NKLEAVES/en>

Really nice problem! Its strict timelimit made me a little nervous but I still like it :]

Really nice problem! Its strict timelimit made me a little nervous but I still like it :]

Could you give a hint how to solve it ?

up :). Any hints, please, anyone.

May be it will sound stupid, but will BS on the max limit for each pile would work?

Edit: Ignore it, ArdianKp's solution seems to be interesting. Can you please enlight us more?

Let the number of leaves in location i be w_i . First, I ignore the first hole since it is always there.

If we do not put any hole, then the total cost = $w_1 + 2w_2 + 3w_3 + \dots + w_n$. If we put one hole in position 4, then the total cost will be reduced by $4 \cdot (w_4 + w_5 + w_6 + \dots + w_n)$. If we put another hole in position 6, then the total cost will be reduced by $(6-4) \cdot (w_6 + w_7 + \dots + w_n)$.

Therefore, let s_i be the sum of w_i from i to n , if we put holes in position a, b, c, d then the total reduced cost is

$a \cdot s_a +$
 $(b-a) \cdot s_b +$
 $(c-b) \cdot s_c +$
 $(d-c) \cdot s_d,$
 and our objective is to maximize this sum.

Now, let $DP[K-1, b]$ be the optimal placing of $(K-1)$ holes when the first is in b (e.g. $DP[3, b] = (c-b) \cdot s_c + (d-c) \cdot s_d$, for optimal choice of c and d), then $DP[K, a] =$ the minimum of $(b-a) \cdot s_b + DP[K-1, b]$, for all possible b .

We can see that $(b-a) \cdot s_b + DP[K-1, b]$ form a line equation with gradient $-s_b$, and offset $b \cdot s_b + DP[K-1, b]$.

Hence, to calculate $DP[K, a]$ for all a , first we built the line equation of all b , extract the "promising lines" ($g_i < g_j$ and $o_i > o_j$, where g and o are gradient and offset respectively). Having all the lines, we can do line-sweep to find the optimal b for all a in $O(n)$.

Well wont it take $O(n \lg n)$ in each step? so total run time according to me should be, $kn \lg n$? am i wrong? if so then how to do that in $O(n)$ instead of $n \lg n$?

it's $O(N)$ because of the lines are automatically sorted (the gradient is in decreasing order (or increasing depend on the direction you see)).

Anyway you got the idea :)

Hmm... Ok I will code it and let you know my condition. Anyway thanks for the nice problem and nice solution too :)

If I remember correctly, the task 'Cutting A Greed' from IOI 2006 practice, is a good problem to practice on. The sad thing is that it doesn't come with test cases! Anyway [here](#) you can find the problem statement.

given set of points and gradients, find the minimum y-intercept for each gradient. Ignoring the sorting, this problem can be solved in $O(n)$.

Can you describe the algorithm... I don't know how to solve this in $O(n)$

The algorithm has been described by **ardiankp** above. It's a bit high level but it will make sense after several hours ;). Just to add more details so that it's easier to understand:

Initially, you have a simple DP $O(N^2 * K)$:

$s[i] = \text{sum of weights from } w[i] \text{ to } w[n]$

```
for i:=1 to N do
```

```
  dp[1][i] = 0;
```

```
for k:=2 to K do
```

```
  for a:=1 to N do
```

```
    for b:=a+1 to N do
```

```
      dp[k][a] = max(dp[k][a], (b-a) * s[b] + dp[k-1][b]);
```

all = sum of s from $s[1] \dots s[n]$

minCost = all - $w[1]$ - $dp[K][1]$;

We want to eliminate the innermost loop "for b:=a+1 to N do".

Each value **b** here is actually a line equation:

$dp[k][a] = (b-a)*s[b] + dp[k-1][b];$

$dp[k][a] = (-s[b]) * a + s[b] * b + dp[k-1][b];$

is a line $y = m * x + c$

We know all the value for $m[b] = -s[b]$ and $c[b] = s[b] * b + dp[k-1][b]$ from the pre-calc and the previous DP iteration. Hence, we have N line equations which are represented by $m[b]$ and $c[b]$.

Since we want the $y = dp[k][a]$ value to be maximum, we are interested only to those lines that has the highest y value for all x. The good thing is all lines is already sorted by it's gradient $m[b]$ in increasing order. Therefore we can omit the sorting and do the convex-hull-like algorithm in $O(N)$.

Having this, we can improve the DP above to $O(N * K)$:

$s[i] = \text{sum of weights from } w[i] \text{ to } w[n]$

```
for i:=1 to N do
```

```
  dp[1][i] = 0;
```

```
for k:=2 to K do {
```

```
  select the top-most lines (m,c)
```

```
  from all line equations (1..N)
```

```
  using convex-hull-like algorithm
```

```
  i = 0;
```

```
  for a:=1 to N do {
```

```
    dp[k][a] = max(dp[k][a], m[i] * a + c[i]);
```

```
    advance i as necessary to maintain
```

```
    line i as the top-most line
```

```
  }
```

```
}
```

all = sum of s from $s[1] \dots s[n]$

minCost = all - $w[1]$ - $dp[K][1]$;

Hope that helps

I have recently started practicing problem from TopCoder on DP . I have encountered some amazing problem which teach me something.

Apart from above high level stuff , there are quite easy techniques which used with dp wonders in problem solving .

Like this <http://forums.topcoder.com/?module=Thread&threadID=625789&start=0&mc=11> Instead of Going to any bottom up or top down if you go to all possible next state from current state it is more easy to think

Also this one http://www.topcoder.com/stat?c=problem_statement&pm=8538 which beautifully uses bit masking with dp.

I have also a list of problems from here <http://forums.topcoder.com/?module=Thread&threadID=625789&start=0&mc=11> . I am currently solving problem in green and yellow.

My question you guys have much experience then me , can post some question , analysis or tutorial which will be really helpful to understand other techniques used with dp.
